

Figure 1: Bar problem

**Problems 1 and 4 are for practice. These problems are shown in gray. If you return them and the solution, they will have a perfunctory grading up to the maximum extra credit shown.**

1. **10 extra credit Points** Obtain an approximate solution of the following boundary value problem using spectral Galerkin method (that is trial functions are polynomials over the entire domain):

$$u''(x) + u(x) + x = 0 \quad (1a)$$

$$u(0) = 0 \quad (1b)$$

$$u(1) = 0 \quad (1c)$$

- (a) Derive the weak statement for the problem. **(20 Points)**
  - (b) Using **one** appropriate quadratic polynomial trial function, find an approximate solution of the form  $\phi(x) = \alpha_0 + \alpha_1 x + \alpha_2 x^2$  (i.e., find appropriate  $\alpha_i$ ) such that  $\phi(x) = \phi_1(x)$  satisfies all essential boundary conditions. Next, find an appropriate  $\phi_p(x)$  that satisfies all homogeneous essential BCs and from which seek solution in the form  $u^h(x) = \phi_p(x) + \phi(x)a$ . Your weak statement solution involves only one unknown  $a$ . You should not directly plug  $\phi(x) = \alpha_0 + \alpha_1 x + \alpha_2 x^2$  with  $\alpha_i$  as unknowns in the weak statement. **(25 Points)**
  - (c) What is the error between approximate solution and the exact solution  $u(x) = -x + \frac{\sin(x)}{\sin(1.0)}$  at  $x = 0.5$ :  $e(0.5) = u^h(0.5) - u(0.5)$ ? **(5 Points)**
2. **80 Points** An axially loaded bar, fig. 1, carries a distributed load over one quarter of its length and has a small gap at one end as shown in the following figure. Divide the bar into appropriate number of elements and compute displacements in the bar. Note that if the load is large enough to close the gap then the gap can be treated as a known displacement boundary condition. Assume  $L = 500$  mm,  $A = 25$  mm<sup>2</sup>,  $E = 20,000$  N/mm<sup>2</sup>,  $q = 400$  N/mm, (a) gap = 1 mm, (b) gap = 20 mm.

Hints:

- Make sure you use you use a local (element-centered) approach. In fact, for no problems from this point on, you'll use a global approach. That is, you form element level force and stiffness and assemble them to the global force and stiffness.
- Break the domain into 3 elements of lengths  $L/4$ ,  $L/4$ , and  $L/2$  from left to right.
- For element 1 and 3 (left and right ones)  $f_r = 0$ . For the middle element  $q_1 = q_2 = \bar{q}$ . You'll use the  $f_r = r_e[q_1 q_2]^T$  formula.
- You don't know if the gap closes or not for a given loading condition. You'll solve the problem as if there is no wall on the RHS of the domain. Get the far side displacement. If smaller than the gap, your assumption is correct. If not, you need to re-do the problem, this time the far right being a Dirichlet BC with the prescribed displacement equal to the gap.

3. **60 Points** Consider an 1D bar element with  $E = 1$ ,  $L = 1$ , and  $A(x) = 1 + x$ .
- (10 Points)** Obtain the stiffness matrix for finite element method, using equation (373) in section 2.2 of course notes.
  - Obtain the stiffness matrix using the direct method using the methodology described in equations 307-308 of section 2.2 (equations 375-376). Include all the steps in equation 307 in your derivation.
  - (20 Points)** Comparison of the two approaches: i) Compare the stiffness matrices; ii) Assume that  $u_1 = 0, u_2 = 1$  (the end point displacements). Plot the displacement field, strain, and stress for the two methods; iii) (extra credit) compare internal energies  $\mathcal{E} = \int_0^1 \frac{1}{2} E(x) A(x) \epsilon^2(x) dx$  ( $\epsilon = \frac{du}{dx}$ ). **(30 Points)** + **(20 Points)** (extra credit)

Figure 2: 3 dof truss with an angled support

4. **20 extra credit Points** For the truss shown in figure the prescribed dofs are:  $\bar{U}_1 = \bar{U}_2 = \bar{U}_4 = \bar{U}_5 = 0; \bar{U}_3 = \frac{1}{10}$ . For all four truss members  $E = 1, A = 1$ . Other information is provided in the figure 3.
- Form element force vectors and stiffness matrices. Note that for elements  $e_2$  and  $e_4$  two different coordinate systems are used at the two ends and an equation of the form (394) in section 2.3 should be employed. Also, the angle  $\theta$  in the figure is the angle that the bar makes with  $x$  axis and is different from  $\theta_1$  and  $\theta_2$  in the figure used for equation (394).
  - Form global stiffness matrix, total force and solve for global  $\mathbf{U}_f$ .
  - Summarize element local displacements and obtain their axial force.
  - Obtain support reactions at  $B$  (2),  $C$  (1), and  $D$  (2).

Hints:

- Note that integrals for  $k^e$  are represented in terms of  $\xi$  and area is given in terms of  $x$ . You need to use  $x(\xi) = x_1 N_1(\xi) + x_2 N_2(\xi)$  to obtain  $A(\xi) = A(x(\xi))$ .

5. **80 Points** In figure 5 **Frame element**  $e_2$  is hinged to **truss element**  $e_1$ . For the frame element, a concentrated moment  $\bar{M} = 1$  is applied at  $x = 0.75$  and a **upward** (for the beam part of the frame element) distributed load  $q = x$  is applied over the length of the frame.

For your reference,  $f_r$  of the frame element has two parts: 1) From  $\bar{M}$  which can be calculated and shown to be,

$$f_{r,M}^{e_2} = \begin{bmatrix} -\frac{9}{50} \\ \frac{9}{16} \\ \frac{33}{16} \end{bmatrix}$$

2) from  $q$ , where we need to use a  $4 \times 2$  matrix multiplied by  $2 \times 1$  end node upward  $q$  values. You need to add both  $f_r$  to get the  $f_r$  of this element.

Figure 3: Frame and truss example.

- Number free and prescribed dofs. **(10 Points)**
- Form element force vectors and stiffness matrices. **(20 Points)**
- Form global stiffness matrix, total force and solve for global  $\mathbf{U}_f$ . **(20 Points)**
- Obtain displacement ( $y$ ), rotation ( $\theta = \frac{dy}{dx}$ ), and moment ( $M = EI \frac{d^2y}{dx^2}$ ) for the frame element at  $x = 0.5$ . Note that  $y(\xi) = \sum_{i=1}^4 N_i^e(\xi) a_i^e$ . Also, since  $\mathbf{B}^e = \frac{d^2 \mathbf{N}^e}{dx^2} \Rightarrow M = EI \sum_{i=1}^4 B_i^e(\xi) a_i^e$ . **(30 Points)**
